ABSTRACT

Plastic pipes, tubes or catheters are extruded by pressure-driven flows through annular dies. Whereas die lands are straight, the section connecting the die land to the extruder either converges or diverges, converging when the product is smaller than the extruder barrel, and diverging when larger. In this paper, we carefully consider the converging or diverging connecting flows, in spherical coordinates, for the most common configuration: the Newtonian pressure-driven flow through the annulus between two co-apical coaxial cones. We derive the exact analytical solution for the velocity profile, and then use this to arrive at the exact analytical solution for the temperature rise caused by viscous heating. We care about this rise because it often governs maximum throughput, since pipe makers must protect the melt from thermal degradation. We find that both the velocity profile, and the temperature profile, peak over the same conical surface, and this surface is nearer the inner die wall. We also provide analytical expressions for the nonlinear pressure profile and the die cooling requirement. We find that this cooling requirement is always higher on the inner cone.

Keywords: Coaxial co-apical conical dies, converging annular die, diverging annular die, extrudate temperature rise, pipe die cooling requirement, pipe extrusion throughput, plastic pipe extrusion, viscous dissipation, viscous heating.

I. INTRODUCTION

Plastic pipes, tubes, catheters or hollow fibers are extruded by pressure-driven flows through annular dies. Whereas die lands are straight, the section connecting the die land to the extruder either converges or diverges, converging when the product is smaller than the extruder barrel, and diverging when larger. We call flows that converge or diverge, verging flows. In this paper, we carefully consider the verging connecting flow, in spherical coordinates, for the most common configuration: the pressure-driven flow through the annulus between two co-apical coaxial cones. We explore the analytical solution for the velocity profile, and then use this to calculate the temperature rise caused by viscous dissipation. We care about this rise because it often governs maximum throughput, since pipe makers must keep the melt from degrading. In this paper, we focus specifically on highly viscous nearly Newtonian polymer melts such as extrusion grades of condensation polymers. These would include nylon, polycarbonate or polyester.

TABLE 1 classifies the literature on pressure-driven converging or diverging annular flow. Whereas the straight annular pipe die lands are rarely concentric (a sag compensating measure [1,2,3,4,5,6,7,8,9,10,11,12]), connecting verging flow geometries are normally co-apical and coaxial. TABLE 2 lists our dimensional variables, and TABLE 3, the dimensionless ones.

Parnaby and Worth ([13]; see also Problems 5-37 and 5-38 of [14]) used cylindrical coordinates to arrive at the approximate analytical solution for co-apical and coaxial converging annular flow of Newtonian fluids, rewritten in spherical coordinates defined in Figure 1 and TABLE 2 and mindful of our erratum in [13]:

\[
\frac{2\mu Q(1-\kappa^3)}{3\pi \Omega r^3_i \cos^3 \theta \tan^4 \theta} < \Delta p < \frac{2\mu Q(1-\kappa^3)}{3\pi \Omega r^3_i \cos^3 \theta \tan^4 \theta}
\]

where:

\[
\kappa = \frac{r_i}{r_o}
\]

(2)

and for \((\tan \theta_i / \tan \theta_o) > 0.6\):

\[
\Omega = \frac{1}{\xi} \left( 1 + \frac{\tan \theta_i}{\tan \theta_o} \right) \left( 1 - \frac{\tan \theta_i}{\tan \theta_o} \right)^3
\]

(3)

Dijksman and Savenije used the special toroidal coordinates to find exact analytical solutions for converging and diverging non-co-apical and coaxial annular Newtonian flow [15]. By non-co-apical we mean that the conical walls do
not share the same apex. They even rewrote the equations of continuity and motion in toroidal coordinates (see Appendices I and II of [15]). For co-apical converging Newtonian flows, their equation for the velocity (Eq. (4.9) of [15]), rewritten in spherical coordinates, defined in Figure 1 and TABLE 2, is:

\[
v_r = \frac{-3Q(\theta - \theta_i)(\theta - \theta_i - \theta_o)}{\pi r^2 \theta_i^3 \sin \theta_i}
\]

(4)

However, Eq. (4) does not satisfy the boundary condition at \( \theta_o \) given by Eq. (34). Hence, Eqs. (4.9) and (4.10) of [15] should not be used.

Liang also reached analytical solutions for converging annular flow of power-law fluids [16]. For our case, Liang exact analytical solution written using the variables defined in Figure 1 and TABLE 2 is:

\[
\Delta p = \frac{Q\mu}{3\pi r_i^3 f_c} (1 - \kappa^3)
\]

(5)

where \( \kappa \) is defined in Eq. (2) and:

\[
f_c = \frac{1}{2} \left[ \left( \theta_i - \theta_i \right)^3 \sin \theta_i + \left( \theta_o - \theta_i \right)^3 \sin \theta_o - \frac{1}{2} \left( \theta_i - \theta_i \right)^2 \left( \cos \theta_i - \cos \theta_o \right) \right]
\]

(6)

where \( \theta = \text{rad} \), and in which \( \theta_c = \frac{1}{2} \left( \theta_i + \theta_o \right) \) for both \( u_r(r, \theta_i) = 0 \) and \( u_r(r, \theta_o) = 0 \).

In this work, we use spherical coordinates to analyze viscous dissipation in pressure-driven flow through a *verging* annular plastics extrusion die. We find exact analytical solutions for the steady state velocity and temperature rise profiles.

II. METHOD

We consider molten Newtonian plastics, flowing through *verging* conical annular dies. Figure 1 shows these annuli, between two coaxial co-apical cones. Our analysis follows the transport phenomena approach. We explore the analytical solution for the velocity profile, and then use this to calculate the temperature rise caused by viscous dissipation.

III. ANALYSIS

A. Velocity profile

a) Physical intuition
Figure 2 and Figure 3 show that the molten plastic moves in the $r$-direction only:

$$v_\theta = v_\phi = 0$$  \hspace{1cm} (7)

where:

$$\mathbf{v} = (v_r(r, \theta), 0, 0); v_r(r, \theta) \leq 0$$  \hspace{1cm} (8)

for converging flows, and:

$$\mathbf{v} = (v_r(r, \theta), 0, 0); v_r(r, \theta) \geq 0$$  \hspace{1cm} (9)

for diverging.

b) **Equation of continuity in spherical coordinates $(r, \theta, \phi)$**

From the equation of continuity (Eq. B.4-3 of [17]), for constant density, and using Eqs. (7), we get:

$$v_r = \frac{C(\theta)}{r^2}$$  \hspace{1cm} (10)

and differentiating, gives:

$$\frac{\partial v_r}{\partial r} = \frac{-2C(\theta)}{r^3}$$  \hspace{1cm} (11)

which we will use to simplify the $rr$-component of the rate of deformation tensor, and also, to simplify the $r$-component of the equation of motion.

c) **Equations of motion in spherical coordinates $(r, \theta, \phi)$**

The $r$-component of the equation of motion (Eq. B.5-7 of [17]), after applying Eq. (7) and $\phi$ symmetry, reduces to:

$$\rho v_r \frac{\partial v_r}{\partial r} = -\frac{\partial p}{\partial r} - \left[ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \tau_{rr} \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( \tau_{\theta r} \sin \theta \right) - \frac{\tau_{\phi \phi}}{r} \right] - \rho g \cos \theta$$  \hspace{1cm} (12)

Each relevant component of the rate of deformation tensor (§B.1 of [17]), simplified with Eqs. (8), (9), (10) or (11), then gives:

$$\dot{\gamma}_r = 2 \frac{\partial v_r}{\partial r} = \frac{-4C}{r^3}$$  \hspace{1cm} (13)
\[ \dot{\gamma}_{\theta\theta} = 2 \left( \frac{1}{r} \frac{\partial v}{\partial \theta} + \frac{\nu}{r} \right) = 2 \frac{\nu}{r} = \frac{2C}{r^3} \]

\[ \dot{\gamma}_{\phi\phi} = 2 \left( \frac{1}{r \sin \theta} \frac{\partial v}{\partial \phi} + \frac{\nu}{r} + \frac{v}{r} \cot \theta \right) = 2 \frac{\nu}{r} = \Delta_{\theta\theta} \]

\[ \dot{\gamma}_{r\theta} = r \frac{\partial}{\partial r} \left( \frac{\nu}{r} \right) + \frac{1}{r} \frac{\partial v}{\partial \theta} = \frac{1}{r} \frac{\partial}{\partial \theta} \left[ \frac{C(\theta)}{r^2} \right] = \frac{1}{r^3} \frac{\partial C}{\partial \theta} \]

Hence \( \tau_{\theta\theta} = \tau_{\phi\phi} \), so that combining Eq. (12) with Eqs. (10) and (11) yields:

\[ -2 \rho \frac{C^2}{r^5} = \frac{-\partial p}{\partial r} - \left[ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \tau_{\phi} \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( \tau_{\theta} \sin \theta \right) - 2 \frac{\nu}{r} \right] - \rho g \cos \theta \quad (15) \]

\[ \text{d) Eliminating stresses} \]

Combining Eqs. (13) and (14) with the constitutive equation for Newtonian fluids:

\[ \tau_{r\theta} = -\mu \dot{\gamma}_{r\theta} \quad (16) \]

yields:

\[ \tau_{r\theta} = \frac{4\mu C}{r^3} \]

\[ \tau_{\theta\theta} = \frac{2\mu C}{r^3} \]

\[ \tau_{r\theta} = -\frac{\mu}{r^3} \frac{\partial C}{\partial \theta} \]

We can eliminate the stresses from Eq. (15), and since \( C \) depends on \( \theta \) only:

\[ -2 \rho \frac{C^2}{r^5} = \frac{-\partial p}{\partial r} + \frac{\mu}{r^4 \sin \theta} \frac{d}{d \theta} \left( \frac{dC}{d \theta} \sin \theta \right) - \rho g \cos \theta \quad (18) \]

Neglecting both fluid inertia and gravity, we get:

\[ 0 = \frac{-\partial p}{\partial r} + \frac{\mu}{r^4 \sin \theta} \frac{d}{d \theta} \left( \frac{dC}{d \theta} \sin \theta \right) \quad (19) \]

for which the variables easily separate:

\[ r^4 \frac{dp}{dr} = \frac{\mu}{\sin \theta} \frac{d}{d \theta} \left( \frac{dC}{d \theta} \sin \theta \right) \quad (20) \]

and thus:

\[ r^4 \frac{dp}{dr} = C_1 \quad (21) \]

which is easily integrated to give the (nonlinear) pressure profile:
\( p = C_4 - \frac{C_1}{3r^3} \) \hspace{1cm} (22)

from which we learn that the pressure depends at most on \( r \), and which is subject to the pressure boundary conditions:

\( p_o = C_4 - \frac{C_1}{3r_o^3} \) \hspace{1cm} (23)

\( p_i = C_4 - \frac{C_1}{3r_i^3} \) \hspace{1cm} (24)

where, for converging flows, the outer pressure must exceed the inner:

\( p_o > p_i \) \hspace{1cm} (25)

and, for diverging:

\( p_i > p_o \) \hspace{1cm} (26)

Solving Eqs. (23) and (24):

\[ C_1 = \frac{3(p_o - p_i)r_i^3}{1 - \kappa^3} \] \hspace{1cm} (27)

\[ C_4 = \frac{p_o - \kappa^3 p_i}{1 - \kappa^3} \] \hspace{1cm} (28)

where \( \kappa \) is defined in Eq. (2). Hence:

\[ p = \frac{1}{1 - \kappa^3} \left[ p_o - \kappa^3 p_i - \frac{(p_o - p_i)r_i^3}{r^3} \right] \] \hspace{1cm} (29)

Returning to the right side of Eq. (20) gives:

\[ \frac{d^2C}{d\theta^2} + \cos \theta \frac{dC}{d\theta} - \frac{C_1}{\mu} \] \hspace{1cm} (30)

which has the general real solution:

\[ C = \frac{-C_1}{2\mu} (a + b) - C_2 (a - b) + C_3 \] \hspace{1cm} (31)

where:

\[ a = \log (1 + \cos \theta) \] \hspace{1cm} (32)

\[ b = \log (1 - \cos \theta) \] \hspace{1cm} (33)

and where \( C = C_2 = C_3 = C_1/\mu \) and \( E/\mu \).

Eq. (31) is subject to the no-slip boundary conditions:

\[ C(\theta_o) = C(\theta_i) = 0 \] \hspace{1cm} (34)

and hence:

\[ 0 = \frac{-C_1}{\mu} (a_o + b_o) - 2C_2 (a_o - b_o) + 2C_3 \] \hspace{1cm} (35)
\[ 0 = \frac{-C_1}{\mu} (a_i + b_i) - 2C_2 (a_i - b_i) + 2C_3 \]  
(36)

where \( C_1 \) is given by Eq. (27), and where:

\[ a_o = \log \left(1 + \cos \theta_o \right) \]  
(37)

\[ b_o = \log \left(1 - \cos \theta_o \right) \]  
(38)

\[ a_i = \log \left(1 + \cos \theta_i \right) \]  
(39)

\[ b_i = \log \left(1 - \cos \theta_i \right) \]  
(40)

Solving Eqs. (35) and (36) and substituting the results into Eq. (31) gives:

\[ C = \frac{3(p_o - p_i) r_i^3}{2\mu(1 - \kappa^2)} \left[ -(a + b) + \frac{(a_o + b_o - a_i - b_i)}{(a_o - b_o - a_i + b_i)}(a - b) + 2\frac{a_o b_o - a_i b_i}{(a_o - b_o - a_i + b_i)} \right] \]  
(41)

Substituting this into Eq. (10) we get the exact solution for the velocity profile in spherical coordinates for pressure-driven flow through conical co-apical coaxial annulus:

\[ v_r = \frac{3(p_o - p_i) r_i^3}{2\mu(1 - \kappa^2)} \left[ -(a + b) + \frac{(a_o + b_o - a_i - b_i)}{(a_o - b_o - a_i + b_i)}(a - b) + 2\frac{a_o b_o - a_i b_i}{(a_o - b_o - a_i + b_i)} \right] \]  
(42)

be it converging or diverging. Differentiating Eq. (42) and solving for \( \theta_{\min,v_r} \) we get:

\[ \theta_{\min,v_r} = \arccos \left( \frac{-a_o - b_o + a_i + b_i}{a_o - b_o - a_i + b_i} \right) \]  
(43)

For converging (and diverging) flows, \( \theta_{\min,v_r} < (\theta_i + \theta_o)/2 \), with \( \theta_i, \theta_o \in [0; \pi/2] \), and thus the minimum (and maximum) velocity cones are nearer the inner surface than the outer. This is why shear rates \( \dot{\gamma}_{r\theta} \) (and thus the shear stresses \( \tau_{r\theta} \)) on the inner cone are higher than on the outer (for both converging and diverging flows).

We now turn our attention to the \( \phi \)-component of the equation of motion (Eq. B.5-9 [17]) which, following Subsections III.Ac and III.Ad), and since we are neglecting gravity, gives:

\[ \rho \left( \frac{\partial v_\phi}{\partial t} + v_r \frac{\partial v_\phi}{\partial r} + \frac{v_\theta}{r} \frac{\partial v_\phi}{\partial \theta} + \frac{v_\phi}{r \sin \theta} \frac{\partial v_\phi}{\partial \phi} + \frac{v_\phi v_r + v_\phi v_\theta \cot \theta}{r} \right) = \frac{-1}{r \sin \theta} \frac{\partial p}{\partial \phi} - \left[ \frac{1}{r^3} \frac{\partial}{\partial r} \left( r^3 \tau_{r\phi} \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( \tau_{\phi\theta} \sin \theta \right) + \frac{1}{r \sin \theta} \frac{\partial \tau_{\phi\phi}}{\partial \phi} + \frac{\tau_{\phi\phi} \cot \theta}{r} \right] \]  
(44)

Eliminating the stresses using:
\[ \tau_{r\phi} = \tau_{\phi\theta} = 0 \]
\[ \tau_{\phi\phi} = -\frac{2\mu C}{r^3} \]

we get,
\[ \frac{\partial p}{\partial \phi} = 0 \]  
(46)

from which we learn that the pressure does not depend on \( \phi \).

Similarly, for the \( \theta \)-component (Eq. B.5-8 [17]), by following Subsections III.Ac) and III.Ad) we get:
\[
\rho \left( \frac{\partial v_\theta}{\partial t} + v_r \frac{\partial v_\theta}{\partial r} + \frac{v_\theta}{r} \frac{\partial v_\theta}{\partial \theta} + \frac{v_\phi}{r \sin \theta} \frac{\partial v_\theta}{\partial \phi} - \frac{v_r v_\theta - v_\phi^2 \cot \theta}{r} \right) \\
= -\frac{1}{r} \frac{\partial p}{\partial \theta} \left[ \frac{1}{r^3} \frac{\partial}{\partial r} \left( r^3 \tau_{r\theta} \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( r \tau_{\phi\theta} \sin \theta \right) + \frac{1}{r \sin \theta} \frac{\partial \tau_{\phi\phi}}{\partial \phi} - \frac{\tau_{\phi\phi} \cot \theta}{r} \right] 
\]

(47)

and then using:
\[
\tau_{r\theta} = \tau_{\phi\phi} = -\frac{2\mu C}{r^3} \\
\tau_{r\phi} = -\frac{\mu C}{r^3} \frac{\partial C}{\partial \theta} \\
\tau_{\phi\theta} = 0 
\]

to eliminate the stresses gives:
\[ \frac{\partial p}{\partial \theta} = \frac{2\mu}{r^3} \frac{dC}{d\theta} \]  
(49)

and integrating yields:
\[ p = \frac{2\mu C}{r^3} + C_5(r) \]  
(50)

Substituting Eq. (29) into Eq. (50) gives:
\[ \frac{1}{1-K^3} \left[ p_o - K^3 p_i - \frac{(p_o - p_i) r_i^3}{r^3} \right] = \frac{2\mu C}{r^3} + C_5(r) \]  
(51)

Solving for \( C_5 \) at \( \theta = \theta_o \) we get:
\[ C_5 = \frac{1}{1-K^3} \left[ p_o - K^3 p_i - \frac{(p_o - p_i) r_i^3}{r^3} \right] = p(r) \]  
(52)

Substituting Eqs. (27), (41) and (52) into Eq. (50) yields the two dimensional nonlinear pressure profile:
\[ p(r, \theta) = \frac{(p_o - p_i) r_i^3}{(1-K^3) r^3} (A - 1) + \frac{p_o - K^3 p_i}{1-K^3} \]  
(53)

with:
\[ A(\theta) = 3 \left[ -(a+b) + \left( \frac{a_o+b_o-a_i-b_i}{a_o-b_o-a_i+b_i} \right)(a-b) + 2 \left( \frac{a_o b_i - a_i b_o}{a_o-b_o-a_i+b_i} \right) \right] \] (54)

For most plastics extrusion die designs:
\[ A = 1 \] (55)

Therefore Eq. (53) reduces to Eq. (29) and our assumption that \( p \) depends on \( r \) only [see Subsection III.Ad] is confirmed.

e) Nondimensional velocity and pressure

We begin our nondimensionalization by rearranging:
\[ \xi = \frac{\theta - \theta_i}{\theta_o - \theta_i} \] (56)

from TABLE 3, to give:
\[ \theta = \xi(\theta_o - \theta_i) + \theta_i \] (57)

which, substituted into Eqs. (32) and (33), yields:
\[ a = \log \left[ 1 + \cos \left( \xi(\theta_o - \theta_i) + \theta_i \right) \right] \] (58)

\[ b = \log \left[ 1 - \cos \left( \xi(\theta_o - \theta_i) + \theta_i \right) \right] \] (59)

Next, in Eq. (41), we let:
\[ B(\xi, \theta, \theta_o) = -(a+b) + \left( \frac{a_o+b_o-a_i-b_i}{a_o-b_o-a_i+b_i} \right)(a-b) + 2 \left( \frac{a_o b_i - a_i b_o}{a_o-b_o-a_i+b_i} \right) \] (60)

so that:
\[ C = \frac{BC_i}{2\mu} \] (61)

Substituting Eq. (27) into Eq.(61), we get:
\[ C = \frac{3B(p_o-p_i)r_i^3}{2\mu(1-\kappa^3)} \] (62)

Using this with TABLE 3 gives:
\[ \bar{C} \equiv \frac{C \mu}{(p_o-p_i)r_i^3} = \frac{3B}{2(1-\kappa^3)} \] (63)

and thus:
\[ C = \frac{\bar{C}(p_o-p_i)r_i^3}{\mu} \] (64)

which we will use below. Also letting:
\[ R = \frac{r - r_i}{r_o - r_i} = \frac{R_o}{1 - \kappa} \]  \hspace{1cm} (65)

so that:
\[ r = r_o \left[ R \left( 1 - \kappa \right) + \kappa \right] \]  \hspace{1cm} (66)

Substituting Eqs. (64) and (66) into Eq. (10), rearranging, and using TABLE 3, we get the dimensionless velocity profile:
\[ \psi = \frac{\nu \mu r_o^2}{(p_o - p_i) r_i^3} = \frac{C}{2 \left( 1 - \kappa^3 \right) \left[ R \left( 1 - \kappa \right) + \kappa \right]^2} = \frac{3B(\xi)}{2 \left( 1 - \kappa^3 \right) \left[ R \left( 1 - \kappa \right) + \kappa \right]^2} \]  \hspace{1cm} (67)

where \( \kappa \) is defined in Eq. (2).

Using TABLE 3 with Eq. (29) and rearranging gives the dimensionless pressure profile:
\[ \mathcal{P} = \frac{p - p_i}{\Delta p} = \frac{1}{1 - \kappa^3} \left[ 1 - \frac{\kappa^3}{\left[ R \left( 1 - \kappa \right) + \kappa \right]^3} \right] ; A = 1 \]  \hspace{1cm} (68)

f) Nondimensional \( \frac{Q}{\Delta P} \)

Integrating Eq. (42) twice, with respect to \( \theta \) and \( \phi \), and then rearranging gives:
\[ \Delta p = \frac{Q \mu \left( 1 - \kappa^3 \right)}{3\pi r_i^3 f_s} \]  \hspace{1cm} (69)

where:
\[ f_s = \left( 1 - \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \left[ a_o \left( 1 + \cos \theta_o \right) - a_i \left( 1 + \cos \theta_i \right) \right] \]
\[ - \left( 1 + \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \left[ b_o \left( 1 - \cos \theta_o \right) - b_i \left( 1 - \cos \theta_i \right) \right] \]
\[ - 2 \left( \cos \theta_o - \cos \theta_i \right) \left( 1 + \frac{a_o b_i - a_i b_o}{a_o - b_o - a_i + b_i} \right) \]  \hspace{1cm} (70)

with \( a_o, b_o, a_i \) and \( b_i \) defined in Eqs. (37) through (40). Eq. (70) is the first main result of this paper. Using TABLE 2 and TABLE 3, we adimensionalize Eq. (69) to get:
\[ \frac{1 - \kappa^3}{3\pi} \frac{Q}{\Delta P} = f_s \]  \hspace{1cm} (71)
Figure 10 illustrates Eq. (71) and shows how the dimensionless flow rate per unit pressure drop, \( f_s \), the changes with the extrusion die shape, \( \theta_i \) and \( \theta_o \). Practitioners can use Figure 10 to get the volumetric flow rate graphically, or the pressure drop (see WORKED EXAMPLE in Section V).

In Figure 11, we will compare the previous approximate solutions of Parnaby and Worth [Eq. (1)] and of Liang [Eq. (5)] with our exact solution [Eq. (71)]. For this, we must nondimensionalize Eqs. (1) and (5) in the same way as our Eq. (71). For Parnaby and Worth [Eq. (1)] we get:

\[
\frac{1 - \kappa^3}{3\pi} \frac{Q}{\Delta(\rho)} < f_c^i < \frac{Q}{\Delta(\rho)} < f_c^o
\]  

(72)

where:

\[
f_c^i = \frac{\Omega \cos^3 \theta \tan^4 \theta}{2}
\]  

(73)

\[
f_c^o = \frac{\Omega \cos^3 \theta \tan^4 \theta}{2}
\]  

(74)

where \( \Omega \) is defined in Eq. (3), and for Liang [Eq. (5)] we get:

\[
\frac{1 - \kappa^3}{3\pi} \frac{Q}{\Delta(\rho)} = f_L
\]  

(75)

with \( f_L \) defined in Eq. (6).

**B. Temperature rise**

In this section we focus on the temperature rise caused by the viscous dissipation associated with the velocity profile given by our exact solution, Eq. (42). Specifically, we consider melt entering the conical die (illustrated in Figure 1, Figure 4 and Figure 5) at a uniform temperature \( T_o \) and with isothermal inner and outer conical surfaces also at \( T_o \). We are, of course, aware that the extrusion die surfaces can be controlled with other thermal boundary conditions. These conditions lie beyond the scope of this work.

**a) Physical intuition**

Figure 4 and Figure 5 show how the temperature profile evolves in the dies for converging and diverging flows. When viscous dissipation matters, the temperature rises as the melt flows from \( r_o \) to \( r_i \) (\( r_i \) to \( r_o \)) for converging
(diverging) flows. Not unlike $v_r(r, \theta)$, the temperature also depends on both $r$ and $\theta$, $T(r, \theta)$. Thus, for converging flows through isothermal die walls we have:

$$\frac{\partial T}{\partial r} < 0$$

and:

$$T(r, \theta) = T(r, \theta_o) = T(r, \theta_i) = T_0$$

whereas for diverging:

$$\frac{\partial T}{\partial r} > 0$$

and:

$$T(r, \theta) = T(r, \theta_o) = T(r, \theta_i) = T_0$$

For both converging and diverging flows, we define:

$$\frac{\partial T}{\partial \theta} \bigg|_{r_{\text{max}}(r)} = 0; \; \theta = \theta_{\text{max},T}(r)$$

which defines the hottest surface in the flowing melt, which is at most a function of $r$.

b) Viscous dissipation term in spherical coordinates $(r, \theta, \phi)$

We begin by combining the general expression for the viscous dissipation in spherical coordinates (Eq. (C) of Table A.7-3 of [17]) with our physical intuition for the velocity, Eqs. (7):

$$(\tau : \nabla v) = \tau_{rr} \left( \frac{\partial v_r}{\partial r} \right) + \tau_{\theta\theta} \left( \frac{v_r}{r} \right) + \tau_{\phi\phi} \left( \frac{v_r}{r} \right) + \tau_{r\theta} \left( \frac{1}{r} \frac{\partial v_r}{\partial \theta} \right) + \tau_{r\phi} \left( \frac{1}{r \sin \theta} \frac{\partial v_r}{\partial \phi} \right)$$

which when combined with the velocity profile and its derivative, Eqs. (10) and (11), gives:

$$(\tau : \nabla v) = \tau_{rr} \left( \frac{\partial v_r}{\partial r} \right) + \tau_{\theta\theta} \left( \frac{v_r}{r} \right) + \tau_{\phi\phi} \left( \frac{v_r}{r} \right) + \tau_{r\theta} \left( \frac{1}{r} \frac{\partial v_r}{\partial \theta} \right)$$

from which we eliminate the stresses using Eqs. (17), (45), $\tau_{rr} = -2\tau_{\theta\theta}$ and $\tau_{\phi\phi} = \tau_{r\theta}$ to get:

$$(\tau : \nabla v) = \frac{-\mu}{r^6} \left[ 12C^2 + \left( \frac{dC}{d\theta} \right)^2 \right]$$

which we will use in Subsection III.B.c), and where the exact solution for $C$ is given by Eq. (41).
c) Equation of energy in spherical coordinates \((r, \theta, \phi)\)

We begin by simplifying the equation of energy written in terms of temperature for an incompressible fluid (Eq. B.8-3 of [17]), with \(\phi\) symmetry for the longitudinal heat flux, \(q_\phi\), gives:

\[
\rho \dot{C}_p v \frac{\partial T}{\partial r} = -\left[ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 q_r \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( q_\phi \sin \theta \right) \right] - (\tau : \nabla v) \tag{84}
\]

Eliminating the heat fluxes using Fourier's law (Eqs. B.2-7 and B.2-8 of [17]) we get:

\[
\rho \dot{C}_p v \frac{\partial T}{\partial r} = k \left[ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( \frac{1}{r} \frac{\partial T}{\partial \theta} \sin \theta \right) \right] - (\tau : \nabla v) \tag{85}
\]

Now, if we assume that axial conduction is negligible (with respect to radial convection):

\[
\rho \dot{C}_p v \frac{\partial T}{\partial r} \gg k \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) \tag{86}
\]

then:

\[
v \frac{\partial T}{\partial r} = \alpha \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} \left( \frac{1}{r} \frac{\partial T}{\partial \theta} \sin \theta \right) - \frac{1}{\rho \dot{C}_p} \left( \tau : \nabla v \right) \tag{87}
\]

where \(\alpha = k / \rho \dot{C}_p\) is the thermal diffusivity (see TABLE 2). Substituting Eqs. (10) and (83) into (87) and rearranging gives:

\[
\dot{C} \frac{\partial T}{\partial r} = \frac{\alpha}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial T}{\partial \theta} \right) + \frac{1}{\rho \dot{C}_p} \frac{\mu}{r} \left[ 12 C^2 + \left( \frac{dC}{d\theta} \right)^2 \right] \tag{88}
\]

which is subject to the boundary conditions given by Eqs. (77) and (79).

d) Dimensionless temperature rise

Using TABLE 2 and TABLE 3, we rewrite Eq. (88) as:

\[
\frac{\partial \Theta}{\partial \mathcal{R}} = \frac{\alpha r_c (1 - \kappa)}{C \sin \theta} \frac{\partial}{\partial \mathcal{R}} \left( \sin \theta \frac{\partial \Theta}{\partial \mathcal{R}} \right) \tag{89}
\]

\[
+ \left[ \frac{\mu}{\rho \dot{C}_p (T_{\text{max}} - T_0)} \right] \mathcal{R}^{(1 - \kappa)} \left[ \mathcal{R} (1 - \kappa) + \kappa \right]^{\frac{3}{2}} \left[ 12 C + \frac{1}{C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]

which uncovers the characteristic time:

\[
\lambda = \frac{\mu}{\rho \dot{C}_p (T_{\text{max}} - T_0)} \tag{90}
\]
so that:

\[
\frac{\partial \Theta}{\partial \mathcal{R}} = \frac{\text{Pé}}{C \sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial \Theta}{\partial \theta} \right) + \frac{\lambda (1 - \kappa)}{r_o^3 \left[ \mathcal{R} \left( 1 - \kappa \right) + \kappa \right]^4} \left[ 12C + \frac{1}{C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(91)

where we have also uncovered the Péclet number:

\[
\text{Pé} = \frac{\alpha \lambda (r_o - r_i)}{r_o^3}
\]  

(92)

Further, using TABLE 3, yields:

\[
\frac{\partial \Theta}{\partial \mathcal{R}} = \frac{\text{Pé}}{C \sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial \Theta}{\partial \theta} \right) + \frac{1 - \kappa}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \left[ 12C + \frac{1}{C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(93)

which we will use presently.

In this Subsection, we begin by neglecting conduction in the \( \theta \) direction, and finish with an exact analytical solution for the temperature rise that is consistent with isothermal, inner and outer die walls, Eqs. (77) and (79). Neglecting conduction in the \( \theta \) direction (\( \text{Pé} = 1 \)), Eq. (93) reduces to:

\[
\frac{\partial \Theta}{\partial \mathcal{R}} = \left( 1 - \kappa \right) \left[ \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right]^4 \left[ 12C + \frac{1}{C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(94)

and has the exact solution:

\[
\Theta = C_0 - \frac{1}{3 \left[ \mathcal{R} \left( 1 - \kappa \right) + \kappa \right]^3} \left[ 12C + \frac{1}{C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(95)

subject to the entrance condition, which for converging flows is:

\[
\Theta \left( \mathcal{R}_0 \right) = \Theta \left( \frac{r_o - r_i}{r_o - r_i} \right) = \Theta \left( 1 \right) = 0
\]  

(96)

so that:

\[
\Theta = \left[ 1 - \frac{1}{\left[ \mathcal{R} \left( 1 - \kappa \right) + \kappa \right]^3} \right] \left[ 4C + \frac{1}{3C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(97)

and for diverging flows is:

\[
\Theta \left( \mathcal{R}_i \right) = \Theta \left( \frac{r_i - r_i}{r_o - r_i} \right) = \Theta \left( 0 \right) = 0
\]  

(98)

so that:

\[
\Theta = \left[ \frac{1}{\kappa^3} - \frac{1}{\left[ \mathcal{R} \left( 1 - \kappa \right) + \kappa \right]^3} \right] \left[ 4C + \frac{1}{3C} \left( \frac{dC}{d\theta} \right)^2 \right]
\]  

(99)
Using Eq. (133), proven in Appendix VIII.B, we get:

\[
\left( \frac{d\varnothing}{d\xi} \right)^2 = \left( \frac{d\varnothing}{d\theta} \right)^2 = 0; A^2 \ll 1
\]  

(100)

which, when applied to Eqs. (97) and (99), gives:

\[
\varnothing = 4C \left[ 1 - \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right]^3; A^2 \ll 1
\]  

(101)

\[
\varnothing = 4C \left[ \frac{1}{\kappa^3} - \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right]^3; A^2 \ll 1
\]  

(102)

where the condition \( A = 1 \) [Eqs. (54) and (55)] on our pressure and velocity [Eqs. (29) and (42)], upon which Eqs. (101) and (102) are based, is already sufficient for \( A^2 = 1 \). The reader is reminded that, for most plastics extrusion die designs, \( A = 1 \).

Since \( C \left( \theta_o \right) = C \left( \theta_i \right) = 0 \), the temperature rise on the die surfaces is also zero, \( \varnothing \left( \theta_o \right) = \varnothing \left( \theta_i \right) = 0 \). In other words, Eqs (101) and (102) are exactly consistent with the isothermal wall boundary conditions Eqs. (77) and (79), which we have yet to use.

Using TABLE 3, Eqs (101) and (102) become:

\[
\varnothing = \left[ \frac{2\lambda \left( p_o - p_i \right) \kappa^3}{\mu \left( 1 - \kappa^3 \right)} \right] \left[ 1 - \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right]^3 A
\]  

(103)

\[
\varnothing = \left[ \frac{2\lambda \left( p_o - p_i \right) \kappa^3}{\mu \left( 1 - \kappa^3 \right)} \right] \left[ \frac{1}{\kappa^3} - \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right]^3 A
\]  

(104)

with \( A \) already defined in Eq. (54). We next differentiate Eqs. (103) and (104) to get the hottest surface in the flowing melt:

\[
\theta_{max,T} = \arccos \left( \frac{-a_o - b_o + a_i + b_i}{a_o - b_o - a_i + b_i} \right)
\]  

(105)

which is conical, and which matches the velocity minimum cone, \( \theta = \theta_{min,v} \), given by Eq. (43). We thus find that the temperature maximum cone \( \theta = \theta_{max,T} \) is nearer the inner surface than the outer.

Using TABLE 3 to rewrite Eqs. (103) and (104) we get:

\[
\varnothing \left( \mathcal{R}, \xi \right) = \mathcal{P} \left( -\frac{\kappa^3}{1 - \kappa^3} \right) \left[ 1 - \frac{1}{\mathcal{R} \left( 1 - \kappa \right) + \kappa} \right] B_i
\]  

(106)
\[ \Theta = \frac{\kappa^3}{1-\kappa^3} \left[ \frac{1}{\kappa^3} - \frac{1}{\frac{\kappa}{3} (1-\kappa) + \kappa^3} \right] B_1 \]  

Eqs. (106) and (107) give the non-dimensional temperature rise for converging and diverging flows respectively, and these are thus the second main result of this work. Eqs. (106) and (107) are exactly consistent with the isothermal wall boundary conditions Eqs. (77) and (79). In Section IV, we will differentiate Eqs. (106) and (107) to calculate the corresponding cooling requirement for conical die surfaces.

IV. RESULTS AND DISCUSSION

In this section, we will illustrate and discuss the main results of our analysis in Section III. We graph the velocity and then the temperature profiles for a specific die design: \( \theta = 10^\circ, \theta_0 = 15^\circ \) and \( \kappa = \frac{1}{2} \). We further compare our exact solution [Eq. (71)] for the throughput per unit pressure drop with prior approximations of Parnaby and Worth [Eq. (72)] and of Liang [Eq. (75)]. We will close Section IV with a dimensionless graph for Eq. (71) that is specifically for practitioners of plastic pipe extrusion die design.

A. Velocity Profile

In the next two Subsections, we discuss Figure 6 and Figure 7, which illustrate the velocity profiles for converging and diverging dies.

a) Converging Flows

The accelerating velocity for converging die flows is negative, and the pressure drop in Eq. (42), is positive. Figure 6 illustrates the velocity profile shape for a particular converging die design. We see that the minimum velocity cone is nearer the inner surface. Using Eq. (43) for the specific die considered, this minimum velocity cone is \( \theta_{\text{min},e} = 12.42^\circ \) which is just inside the midcone, \( \theta = 12.5^\circ \).

b) Diverging Flows

The decelerating velocity for diverging die flows is positive, and the pressure drop in Eq. (42), is negative. Figure 7 illustrates the velocity profile shape for a
specific diverging die design. We see that the maximum velocity cone is nearer the inner surface. Using Eq. (43) for the specific die considered, this maximum velocity cone is \( \theta_{\text{max},v} = 12.42^\circ \) which is just inside the midcone, \( \theta = 12.5^\circ \).

### B. Temperature Rise Profile

In the following two Subsections, we discuss Figure 8 and Figure 9, which illustrate of the temperature rise profiles in the converging and diverging dies.

#### a) Converging Flows

In Figure 8, we plot the dimensionless temperature rise per unit pressure drop, \( \Theta(\rho, \xi)/\Delta p \) which shows the shape of the temperature rise for a specific converging die design. The surface of maximum temperature rise is conical \( \theta_{\text{max},T} = \theta_{\text{min},p} \); 12.42°, which matches the minimum velocity cone. Figure 8 also shows that the wall temperatures are constant at \( T_0 \) and thus the walls are isothermal. To achieve this condition, to compensate for viscous heating, the walls must be cooled.

The expression for the required heat flux for cooling is given by (Eq. B.2-8 of [17]):

\[
q_\theta = -k \frac{1}{r} \frac{\partial T}{\partial \theta} \tag{108}
\]

Substituting Eq. (106), into Eq. (108), and evaluating the result for the inner surface, gives the cooling load requirement:

\[
q_{\theta_i} = \frac{4k\Delta p k^3}{\rho \tilde{C}_p (1 - \kappa^3) \sin \theta_i} \left( \frac{1}{r} \frac{r^3}{r^4} \right) \left( \cos \theta_i + \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \tag{109}
\]

and for the outer surface:

\[
q_{\theta_o} = \frac{4k\Delta p k^3}{\rho \tilde{C}_p (1 - \kappa^3) \sin \theta_o} \left( \frac{1}{r} \frac{r^3}{r^4} \right) \left( \cos \theta_o + \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \tag{110}
\]

From Eqs. (109) and (110), we conclude that the cooling at the inner die cone must be higher than for the outer.
b) Diverging Flows

In Figure 9, we plot the dimensionless temperature rise per unit pressure drop, \(-\Theta(\theta, \xi)\)/\(p\) which shows the shape of the temperature rise for a specific diverging die design. The surface of maximum temperature rise is conical \(\theta_{\text{max}, T} = \theta_{\text{max}, \xi} = 12.42^\circ\), which matches the maximum velocity cone. Figure 9 also shows that the wall temperatures are constant at \(T_0\) and thus the walls are isothermal. To achieve this condition, to compensate for viscous heating, the walls must be cooled.

Substituting Eq. (107), into Eq. (108), and evaluating the result for the inner surface, gives the cooling load requirement:

\[
q_{\theta_i} = \frac{4k\Delta p k^3}{\rho \tilde{C}_p (1-\kappa^3) \sin \theta_i \left( \frac{1}{r^3 \kappa^3} - \frac{r_o^3}{r^4} \right)} \left( \cos \theta_i + \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \quad (111)
\]

and for the outer surface:

\[
q_{\theta_o} = \frac{4k\Delta p k^3}{\rho \tilde{C}_p (1-\kappa^3) \sin \theta_o \left( \frac{1}{r^3 \kappa^3} - \frac{r_o^3}{r^4} \right)} \left( \cos \theta_o + \frac{a_o + b_o - a_i - b_i}{a_o - b_o - a_i + b_i} \right) \quad (112)
\]

From Eqs. (111) and (112), we conclude that the cooling at the inner die cone must be higher than for the outer.

C. Throughput per unit pressure drop

In this section we use Figure 10 to compare our exact solution [Eq. (71)] for the throughput per unit pressure drop with prior approximations of Parnaby and Worth [Eq. (72)] and of Liang [Eq. (75)]. Figure 10 has been constructed for: \(110^\circ \leq \theta_i \leq 15^\circ\), \(\theta_o = 15^\circ\) and \(\kappa = \frac{1}{3}\), which includes the special basis \(\theta_i = 10^\circ\), \(\theta_o = 15^\circ\) and \(\kappa = \frac{1}{3}\) that we used for Figure 6 through Figure 9. For these conditions, Figure 10 shows that whereas the cylindrical approximation of Parnaby and Worth [Eq. (72)] slightly overpredicts the flow rate, Liang [Eq. (75)] grossly overpredicts.

Figure 11 charts the flow rate per unit pressure drop predicted by our exact solution, Eq. (71). We provide this dimensionless graph specifically for plastic pipe extrusion die designers. We will use Figure 11 presently.

V. WORKED EXAMPLE

An engineer gathers the following process details for her polycarbonate pipe extrusion line, and specifically for the converging connection between her
extruder and her straight annular die land: \( \theta_o = 31.0^\circ \), \( \theta_i = 11.0^\circ \), \( r_o = 0.130 \text{ m} \) and 
\( r_i = 0.0500 \text{ m} \), with the throughput of \( \rho Q = -0.0100 \text{ kg/s} \), and the material 
properties at the operating temperature are \( \mu = 1.10 \times 10^7 \text{ Pa s} \), \( \rho = 900 \text{ kg/m}^3 \), 
\( C_p = 1.60 \times 10^7 \text{ J/kg°C} \) and \( k = 0.1 \text{ W/m} \).

She wants to estimate (i) the required pressure drop for the given throughput 
and the (ii) temperature rise in the die.

(i) Using Eq. (54), she first gets 
\[ A(\theta_{\text{min,}}) = A(20.2^\circ) = -0.0941 \] which satisfies 
Eq. (55). She then interpolates Figure 11 with \( \cos \theta_i = 0.982 \) and \( \cos \theta_o = 0.857 \) to 
get, for our exact solution:

\[ f_s = -10^{-2.59} = -0.00257 \] \hspace{1cm} (113)

For this same die, the cylindrical approximations [Eqs. (73) and (74)] give:

\[ f_c^i = -0.0253 \] \hspace{1cm} (114)
\[ f_c^o = -0.0168 \] \hspace{1cm} (115)

and the Liang approximation [Eq. (6)] gives:

\[ f_L = -0.187 \] \hspace{1cm} (116)

Combining Eq. (71) with \( \Delta P = \Delta p r_i / \left( \mu V_{\text{max}} \right) \) and 
\( Q = Q / \left( V_{\text{max}} r_i^2 \right) \) from TABLE 3 
and rearranging gives the pressure drop:

\[ -\Delta p = -Q\mu \left( 1 - k^3 \right) \frac{1 - (r_i/r_o)^3}{3\pi r_i^3 f_s} = \frac{-\rho Q\mu \left( 1 - (r_i/r_o)^3 \right)}{3\pi r_i^3 f_s} \] \hspace{1cm} (117)

Inserting the given die geometry, physical properties and Eq. (113) into Eq. (117):

\[ -\Delta p = \frac{-\left( -0.0100 \text{ kg/s} \right) 1.10 \times 10^7 \text{ Pa s} \left( 1 - \left( 0.0500/0.130 \right)^3 \right)}{3\pi \left( 900 \text{ kg/m}^3 \right) \left( 0.0500 \text{ m} \right)^3 \left( -0.00257 \right)} = -3.81 \times 10^7 \text{ Pa} \] \hspace{1cm} (118)

which the engineer must use to get the required throughput.

(ii) Using Eqs. (106), (90) and \( P = 2\lambda \Delta p / \mu \), \( R = r_i - r_o - r_i \) and 
\( \xi = \theta - \theta_i / \theta_o - \theta_i \) from TABLE 3, she gets the expression for the temperature rise 
in the converging die:

\[ T - T_0 = \left[ \frac{2\lambda \xi}{\rho C_p \left( 1 - k^3 \right)} \right] \left[ 1 - \frac{r_i^3}{r_o^3} \right] A \] \hspace{1cm} (119)

and since the temperature peaks at \( r_i \):

\[ T_{\text{max}} - T_0 = \frac{-2A\Delta p}{\rho C_p} \] \hspace{1cm} (120)
Inserting the physical properties, $A$ and Eq. (118) into Eq. (120), she gets:

$$T_{\text{max}} - T_0 = \frac{-2(-0.0941)3.81 \times 10^7 \text{ Pa}}{(900 \text{ kg/m}^3)1.60 \times 10^3 \text{ J/kg} \cdot \text{°C}} = 4.98 \text{°C} \quad (121)$$

which she can then add to the temperature rise for the die land, to see if her polymer extrudate will exceed its degradation point.

At the end, she verifies the two flow conditions: $\text{Re} = 1$ and $\text{Pe} = 1$. Using Eqs. (130):

$$\text{Re} = \frac{\rho V_{\text{max}} r_i}{\mu} \quad (122)$$

where $V_{\text{max}}$ is calculated using Eq. (42):

$$V_{\text{max}} = \left| v \left( r, \theta_{\text{min}} \right) \right| = \left| \frac{\Delta p A r_i}{2\mu \left( 1 - \left( r_i / r_o \right)^3 \right)} \right| \quad (123)$$

$$V_{\text{max}} = \left| v \left( 0.0500 \text{ m}, 20.2^\circ \right) \right| = \left| \frac{3.81 \times 10^7 \text{ Pa}(-0.0941)0.0500 \text{ m}}{2\left( 1.10 \times 10^7 \text{ Pa} \cdot \text{s} \right)\left( 1 - \left( 0.0500 / 0.013 \right)^3 \right)} \right| = 0.0086 \text{ m/s} \quad (124)$$

she gets, after inserting Eq. (124) and the physical properties into Eq. (122):

$$\text{Re} = \frac{(900 \text{ kg/m}^3)0.0086 \text{ m/s}(0.0500 \text{ m})}{1.10 \times 10^7 \text{ Pa} \cdot \text{s}} = 3.52 \times 10^{-8} \quad (125)$$

which is $\ll 1$.

She then uses Eq. (92) and TABLE 2 to get:

$$\text{Pe} = \frac{k\mu (r_o - r_i)}{\left( \rho C \right)^2 r_o^2 \left( T_{\text{max}} - T_0 \right)} \quad (126)$$

Inserting Eq. (121) and the physical properties into Eq. (126) gives:

$$\text{Pe} = \frac{(0.1 \text{ W/m})1.10 \times 10^7 \text{ Pa} \cdot \text{s}(0.130 \text{ m} - 0.0500 \text{ m})}{(900 \text{ kg/m}^3)^2(1.60 \times 10^3 \text{ J/kg} \cdot \text{°C})^2(0.130 \text{ m})^34.98 \text{°C}} = 3.88 \times 10^{-6} \quad (127)$$

which is also $\ll 1$.

This specific worked example happens to be the one we chose to illustrate in Figure 1.
VI. CONCLUSION

This paper attacks the problem relevant to the connection between a plastics extruder and a pipe extrusion die: the pressure-driven flows, converging or diverging, through the annulus between co-apical coaxial cones. Using the transport phenomena approach we arrive at (1) an exact solution for the velocity profile [Eq. (67)] which we integrate to get (2) the throughput per unit pressure drop [Eq. (75)] and (3) the temperature rise [Eqs. (106) and (107)]. We care about this rise because it often governs maximum throughput, since pipe makers must keep the melt from degrading. Eq. (75) and Eqs. (106)-(107) are the two main results of this work, which we cast in dimensionless terms (see TABLE 3) and which we illustrate in Figure 8, Figure 9 and Figure 11.

Our first main result, the exact solution for the throughput [Eq. (75)] is subject to the dimensionless constraints on the geometry, \( A = 1 \), on the flow field, \( \text{Re} = 1 \) (see Appendix A), that is, that fluid inertia be negligible. We find that these constraints normally apply to plastic pipe extrusion. Our second main result, the exact solution for the temperature rise [Eqs. (106) and (107)], is subject to the dimensionless constraints, \( A = 1 \), and on the flow field, \( \text{Pé} = 1 \), that is, that latitudinal conduction is negligible relative to radial convection. We find this exact solution for the temperature rise to be consistent with isothermal, inner and outer die walls, and we thus calculate the corresponding heat flux requirements for cooling [Eq. (109) through Eq. (112)]. To teach practitioners how to use our main results, we crafted Figure 11 and our two-part worked example (see Section V).

We are unaware of any temperature rise measurements on flow through conical annuli, with which Eqs. (106) and (107) might be compared. Whereas we do find flow rate measurements reported for non-Newtonian fluids pumped through converging dies [16], we find none for Newtonian fluids, with which Eq. (75) might be compared. Moreover, the non-Newtonian flow rate measurements that we do find [16] are for only a slight convergent conical die \( (\theta_o = 12°, \theta_i = 10° \text{ and } \kappa; \frac{1}{2}) \).

In this paper we have focused on the extrusion of pipe, or tubing, or catheters. We close by noting that our work will be at least as useful to those designing diverging dies for blow molding [18,19,20,21].

VII. ACKNOWLEDGMENT

A.J. Giacomin is indebted to the Faculty of Applied Science and Engineering of Queen’s University at Kingston, for its support through a Research Initiation
Grant (RIG). This research was undertaken, in part, thanks to support from the Canada Research Chairs program of the Government of Canada for the Natural Sciences and Engineering Research Council of Canada (NSERC) Tier 1 Canada Research Chair in Rheology. G. Younes acknowledges Mrs. Nadia Moufarrej of the Faculty of Engineering and Architecture of the American University of Beirut for her invaluable support.
VIII. APPENDICES

A. Reynolds number

In this paper, to obtain our main results [Eq. (75)], we neglected fluid inertia. In this appendix, we closely examine this assumption by defining the Reynolds number for the pressure-driven flows, converging or diverging, through the annulus between co-apical coaxial cones. Retaining the inertial terms in Eq. (18) and still neglecting gravity, and since \( p(r) \), gives:

\[
\frac{\rho C}{\mu r} = \frac{r^4}{2C\mu} \frac{dp}{dr} - \frac{1}{2Cs\sin\theta} \frac{d}{d\theta} \left( \frac{dC}{d\theta} \sin\theta \right)
\]

which, using TABLE 3, can be rewritten as:

\[
\text{Re} \equiv \Delta \equiv \frac{r^4}{2C\mu} \frac{dp}{dr} - \frac{R(1-\kappa)+\kappa}{2Cs\sin\theta} \frac{d}{d\theta} \left( \frac{dC}{d\theta} \sin\theta \right)
\]

in which we have uncovered the Reynolds number for pressure-driven flows through the annulus between co-apical coaxial cones:

\[
\text{Re} = \frac{\rho V_{\text{max}} r_i}{\mu}
\]

Since for most polymeric liquids the viscosity \( \mu \) is large, Re \( \ll 1 \).

B. Latitudinal symmetry of \( \mathcal{O} \)

Using TABLE 3 to adimensionalize Eq. (49) and rearranging we get:

\[
\frac{d\mathcal{O}}{d\xi} = \frac{2\kappa^3}{\left[ \mathcal{R}(1-\kappa)+\kappa \right]^3} \frac{d\mathcal{O}}{d\xi}
\]

Since \( \mathcal{O} \) (\( \mathcal{R} \)):

\[
0 = \frac{1}{\left[ \mathcal{R}(1-\kappa)+\kappa \right]^3} \frac{d\mathcal{O}}{d\xi}
\]

and thus:

\[
\frac{d\mathcal{O}}{d\xi} = 0 = \frac{d\mathcal{O}}{d\theta}
\]

since \( \mathcal{O} \) is proportional to \( \mathcal{C} \) and since \( \xi \) is just normalized \( \theta \).
