### Abstract

38 **Objective:** Investigate the role of spinal cord injury (SCI) peer mentorship on quality of life/  
39 participation and test a self-determination theory model that explains the role of SCI peer  
40 mentorship on these outcomes. Mentees (i.e., individuals receiving peer mentorship) were  
41 hypothesized to report greater quality of life (QoL) and participation compared to non-mentees.  
42 Psychological needs were expected to mediate the peer mentorship – outcome relationships.

43

44 **Design:** A static group comparison design.

45 **Setting:** Community.

46

47 **Participants:** A convenience sample of mentees(n= 68) and non-mentees(n= 63) who had a SCI,  
48 above the age of 18, and spoke either English or French.

49

50 **Interventions:** Mentees: at least 4 peer mentorship sessions over the past 5 years; non-peer  
51 mentees: 0 or 1 brief introductory session.

52

53 **Main Outcome Measure(s):** QoL (i.e., life satisfaction and positive and negative affect),  
54 participation (e.g., autonomous indoor; family role) and the psychological needs of autonomy,  
55 competence and relatedness.

56

57 **Results:** No group differences were found but years since injury was a moderator indicating that,  
58 generally, peer mentees living with SCI for longer(~30 years) appear to benefit more from peer  
59 mentorship interactions, compared to non-mentees and mentees living with SCI for ~6 years.  
60 Competence and relatedness mediated the peer mentorship – outcome relationship for QoL and  
61 some participation variables, indicating that peer mentorship predicted competence and  
62 relatedness, which in turn were related to the outcomes.

63

64 **Conclusion(s):** Satisfaction of competence and relatedness needs requires greater attention in  
65 SCI peer mentorship. Years since injury modified the relationship between peer mentorship and  
66 outcomes, which provided new insights on the role of SCI peer mentorship. Further studies are  
67 needed to determine SCI peer mentorship-specific outcomes that are important across the years  
68 since injury spectrum.

69

70 **Key words:** mentorship; quality of life; spinal cord injury; disability; psychological theory;  
participation

71 **Abbreviations**

72 SCI = spinal cord injury

73 QoL = quality of life

74 SDT = self-determination theory

75 ANCOVA = Analysis of covariance

76 bCI = bias corrected confidence intervals

77 YSI = years since injury

78 Spinal Cord Injury (SCI) peer mentors are individuals who, through their lived SCI  
79 experiences, can provide good emotional support and an empathetic understanding to help others  
80 through similar experiences.<sup>1;2</sup> SCI peer mentorship has received growing attention as an  
81 intervention method to enhance quality of life (QoL) and participation (i.e., personal and social  
82 activities/behaviours at home and/or in the community) variables among adults with SCI.<sup>3;4</sup> For  
83 instance, Sherman et al.<sup>3</sup> conducted an examination of an existing US-based SCI peer mentorship  
84 program in a retrospective survey of 62 adults with SCI who received SCI peer mentorship  
85 (mentees; n = 33) or did not (non-mentees). Although the mentoring ended at least a decade  
86 earlier, mentees reported greater life satisfaction and were more involved in  
87 occupational/recreational activities (participation) than non-mentees. Similarly, a recent study of  
88 over 1500 community-dwelling adults with SCI for an average of 18.5 years demonstrated that  
89 the extent to which an individual's need for peer support was met predicted life satisfaction and  
90 participation.<sup>4</sup> In addition, an emerging body of literature has shown the effectiveness of SCI  
91 peer mentorship when such programs target specific behaviours such as wheelchair training  
92 skills<sup>5</sup> and strength-training exercise<sup>6</sup>. Across these peer mentorship studies, mediating variables  
93 (i.e., variables that describe a path between two or more variables) explaining the positive role of  
94 peer mentorship on specific outcomes were not examined. Therefore, the pathways explaining  
95 the relationship between SCI peer mentorship and outcomes such as QoL and participation are  
96 still largely unknown, especially in existing community-based peer mentorship programs.

97 Self-determination theory (SDT) can provide insight into these mediating variables. SDT  
98 is a psychological theory that acknowledges that satisfaction of three psychological needs is  
99 necessary for growth/well-being.<sup>7</sup> The three needs are autonomy (i.e., volition in your actions),  
100 competence (i.e., belief in your actions), and relatedness (i.e., sense of belongingness). In SDT,

101 the social environment plays an important role in the satisfaction of the psychological needs as  
102 has been shown across multiple life domains (e.g., family, work, leisure activities),<sup>8</sup> and among  
103 adults with a physical disability.<sup>9; 10</sup> Given SCI peer mentors are the main agents of the social  
104 environment in a mentor-mentee relationship, SDT is an ideal framework to investigate how  
105 mentorship may relate to QoL and participation variables. Indeed, in SCI-based qualitative  
106 studies, mentees have described peer mentors as having a role in influencing feelings analogous  
107 to competence and relatedness.<sup>11; 12</sup> However, these studies did not examine the mediating role of  
108 the psychological needs on the peer mentorship – QoL/participation relationships. Such insights  
109 could further our understanding of why peer mentorship is related to greater QoL/participation  
110 and inform peer-mentorship programs of the psychological components that mentors could  
111 address.

112 The overall purpose of this study was to examine differences among mentees and non-  
113 mentees on QoL/participation and to test a SDT model where the psychological needs mediate  
114 this relationship. First, it was hypothesized that mentees would report greater QoL and  
115 participation compared to non-mentees.<sup>4</sup> In line with SDT<sup>7</sup>, the second hypothesis was that the  
116 psychological needs would mediate the peer mentorship –QoL/participation relationships.

## 117 **Method**

### 118 **Participants and procedures**

119 A static group comparison study was conducted because we are comparing two groups on  
120 cross-sectional outcomes<sup>13</sup>. Anticipating a moderate-to-large difference (Cohen's  $d = .60$ ) in life  
121 satisfaction between mentees and non-mentees<sup>3</sup>, a power of .80 and an alpha of .05, a sample  
122 size of at least 45 adults with SCI per mentee/non-mentee group (N=90) was required to address

123 hypothesis 1. To test hypothesis 2, a minimum of 100 participants were recruited to reach the  
124 recommended 10-20 participants per parameter in the SDT model (10 parameters).<sup>14</sup>

125 The Quebec provincial organization that represents people with SCI assisted with  
126 recruitment. Mentees were individuals who participated in the organization's peer mentorship  
127 program, which is an individualized, non-structured, program aimed to enhance the  
128 independence/autonomy and QoL of adults with SCI. To minimize participant recall bias  
129 regarding their involvement in the program, two groups were created based on the organization's  
130 peer mentorship records: (a) adults with SCI who received at least four peer mentorship  
131 interactions in the past five years (mentees)<sup>1</sup> and (b) individuals who received zero or only one  
132 short introductory interaction with a peer mentor (non-mentees). Contact lists were generated for  
133 each group and the research team recruited community-dwelling adults with SCI by email and  
134 telephone between January and September 2015. All eligible participants were at least 18 years  
135 old, spoke and/or read French or English, and had a SCI for at least one year and completed the  
136 measures listed below on an online survey. Informed consent was provided and the study was  
137 approved by the first author's research ethics board. Participants were offered a \$25 gift card.

### 138 **Measures**

139 **Demographic and SCI information.** Participants provided demographic and SCI-related  
140 information including: age, gender, marital status, education, level of injury, severity of injury,  
141 years since injury, use of adapted public transportation and ownership of an adapted vehicle.

142 **QoL.** Three QoL variables were assessed: life satisfaction, positive and negative affect.  
143 Using the *Life Satisfaction-11* questionnaire,<sup>15</sup> participants rated their satisfaction with 11 life  
144 situations (e.g., vocational, leisure) on a 6-point scale (1= Very dissatisfying to 6=Very  
145 satisfying). A mean of the 11 items was calculated. This scale had good reliability in this study

146 (Cronbach's  $\alpha = 0.87$ ). The *Positive and Negative Affect Schedule*<sup>16</sup> was used to assess how  
147 participants generally felt by rating a list of 20 adjectives, on a 5-point scale (1= Very  
148 slightly/not at all to 5= Extremely). Means were calculated for the 10 positive (e.g., interested;  
149  $\alpha = .90$ ) and 10 negative affect (e.g., distressed;  $\alpha = .87$ ) adjectives. See supplemental Table I for  
150 confirmatory factor analysis (CFA) supporting the psychometric properties of this scale.

151 **Participation.** Using the Patient-Perceived Participation in Daily Activities  
152 Questionnaire,<sup>17</sup> participants indicated the extent to which they engaged in 26 activities by  
153 selecting one of four option: Yes, as much as I want; Yes, but less than I want; No, but I would  
154 like to; and No, but I don't want to. "No" answers were grouped and labeled as "0" and the  
155 "Yes" options were coded as 2 and 1, respectively, to put more weight on participation rather  
156 than non-participation<sup>4</sup>. Six subscale scores were summed: autonomous indoors participation (7  
157 items: e.g., performing bladder care;  $\alpha = .86$ ); autonomous outdoors participation (6 items: e.g.,  
158 carrying out productive activities that are unpaid;  $\alpha = 0.78$ ); family roles (4 items: e.g. carrying-  
159 out family responsibilities;  $\alpha = 0.67$ ); health (2 items: e.g. maintaining your physical health;  $r =$   
160  $0.23$ ); social relationships (4 items: e.g. maintaining relationships with others;  $\alpha = 0.60$ ); work-  
161 education (3 items: e.g. participating in activities that prepare you to start working in a paid job;  
162  $\alpha = 0.67$ ). Construct validity was previously demonstrated<sup>17</sup> and these reliability estimates mimic  
163 those of another study<sup>4</sup>.

164 **Psychological needs.** The Balanced measure of psychological needs scale was used to  
165 assess the three psychological needs of autonomy, competence and relatedness.<sup>18</sup> Participants  
166 responded on a 5-point scale (1= completely disagree, 5= completely agree). Means of the three  
167 items for each psychological need were calculated (autonomy( $\alpha = .71$ ), competence ( $\alpha = .90$ ) and  
168 relatedness ( $\alpha = .85$ )). See supplemental Table II for CFA.

## 169 **Data analysis**

170 The data were screened for outliers ( $Z \geq 3.29$ ), the normality of the variables  
171 (skewness/kurtosis  $\geq \pm 2$ ) and the degree of missingness. Any univariate outliers were reduced to  
172 one unit higher than the next acceptable value.<sup>19</sup> Non-normally distributed variables were  
173 subjected to a square root transformation. Through a correlation matrix, potential covariates were  
174 identified and controlled for in the respective analyses.

175 Analyses of covariance (ANCOVA) were conducted to examine if mentees reported  
176 greater QoL and participation(hypothesis 1) compared to non-mentees when controlling for  
177 covariates. “In SPSS v.23, we used the PROCESS macro(model 5) developed by Hayes<sup>20</sup> to  
178 conduct mediation and moderation analyses, where the psychological needs were mediators of  
179 the peer mentorship–QoL/participation relationships(hypothesis 2) while YSI retained its  
180 moderation role.” This macro provided 1000 bootstrap 95% bias-corrected confidence intervals  
181 (bCI; corrects bias between bootstrap distribution and sample) to indicate significance.  
182 Bootstrapping is a superior method to test mediation because bCIs are more accurate than  
183 regularly estimated CI and reduce Type 1 error.<sup>21</sup> Significance is determined when the 95% bCI  
184 does not cross 0, which is equivalent to  $p < .05$ .

## 185 **Results**

186 **Preliminary results.** A total of 131 adults with SCI were recruited: 68 mentees; 63 non-  
187 mentees (see supplemental online Figure A for flow chart). Missing data ranged from 0% to 4%  
188 (n=5) on all continuous variables, except for four participation variables (outdoors, health, work-  
189 education, and social relationship) which ranged from 26%(n=34) to 27%(n=35). Missing data  
190 were due to an online survey error where only part of the questionnaire was displayed for the  
191 first 33 participants. After fixing the error, missing data reduced to 0.8% to 3%. Missing data  
192 were imputed in the dataset using expectation maximization at 50 iterations and found to be

193 missing at least at random (Little's MCAR:  $\chi^2(160)= 175.61, p= .19$ ). Such an approach was  
194 used because the majority of our missing data was below 5% (except for four variables), Little's  
195 MCAR test demonstrated that the variables were missing at least at random and to retain power  
196 given the clinical population. Variables were normally distributed (skewness range: -1.30 to  
197 1.10; kurtosis range: -0.92 to 0.95), except for social relationship participation (skewness: -1.29;  
198 kurtosis: 2.18). A square root transformation reduced skewness (0.58) and kurtosis values (-  
199 0.03), but the original data for this participation variable were used because the results were the  
200 same for the transformed and non-transformed variable.<sup>ii</sup> Because years since injury (YSI)  
201 differed between groups (Table 1), it could not be included as a covariate.<sup>22</sup> Covariates reduce  
202 unexplained variance and allow for a more accurate test of the independent variable. When a  
203 covariate differs as a function of the independent variable, it compromises the interpretation of  
204 an ANCOVA.<sup>22</sup> Instead, a moderation analysis can be conducted to examine if the variable  
205 modifies the independent-dependent variable relationship. For these reasons, hypothesis 1 was  
206 tested twice: (a) without YSI and (b) with YSI as a moderator. Moderation was found when the  
207 coefficients of the interaction variable (i.e., SCI peer mentorship\*YSI) were significant. Change  
208 in  $R^2$  indicated the effect size: .02, .13, .26 for small, medium and large, respectively.<sup>23</sup>

209 **Hypothesis 1a: QoL.** All ANCOVAs controlled for sex, paraplegia/tetraplegia, and use  
210 of adapted public transportation. No group differences and very small effect sizes were found for  
211 *life satisfaction, positive affect, and negative affect* (See Table 2 and supplemental Table III-V).  
212 The interaction between YSI and SCI peer mentorship on life satisfaction was significant with a  
213 small to moderate effect size, indicating moderation (Table 3). To interpret moderation, YSI was  
214 graphed as low, medium and high YSI, representing 1 standard deviation below (~6 YSI), equal  
215 to (~18 YSI), and 1 standard deviation above (~30 YSI) the mean, respectively. As illustrated in

216 Figure 1, mentees living with SCI for ~30 years reported slightly greater life satisfaction than  
217 non-mentees while both groups had similar ratings of life satisfaction at low YSI. No moderation  
218 of YSI was found for positive and negative affect.

219 **Hypothesis 1b: Participation.** Specific covariates were controlled for when analyzing  
220 each participation variable. Mentees and non-mentees did not differ on participation variables  
221 (Table 2 & supplemental Tables VI-XI). A significant interaction was found between SCI peer  
222 mentorship and YSI on four participation variables with small and small to moderate effect sizes:  
223 autonomous indoor participation, social relationship, family role, and health (Table 3). The  
224 moderation indicated that autonomous indoor participation was maintained for mentees at  
225 different YSI; however, non-mentees with greater YSI indicated lower levels of autonomous  
226 indoor participation (Figure 2, panel A). In Figure 2 (panels B to D), mentees living with SCI for  
227 ~30 years typically reported greater participation than non-mentees and mentees with lower YSI.  
228 At lower YSI, non-mentees typically reported greater participation than mentees.

229 **Hypothesis 2: SDT Model.** When included in a single model, the psychological needs  
230 exhibited suppression effects on themselves to predict the outcomes. A suppression effect occurs  
231 when the relationship between two variables changes direction (e.g., positive to negative) when  
232 comparing the bivariate correlation with the coefficient of a multivariate regression. For  
233 example, the relationships changed between autonomy and autonomous indoor participation ( $r =$   
234  $.17$ ;  $B = -.01$ ) and between relatedness and family role participation ( $r = .11$ ;  $B = -.23$ ). Conducting  
235 separate models for each psychological need resolved the statistical artifacts caused by  
236 suppression effects because the psychological needs were no longer interacting with each other.

237 After controlling for sex, paraplegia/tetraplegia and use of adapted public transportation,  
238 competence and relatedness mediated the relationship between peer mentorship and life

239 satisfaction, positive affect and negative affect (Table 4; Figure 3; Supplemental Tables XII-  
240 XIV). Specifically, mentees reported slightly greater competence ( $M_{ajd}= 3.71$ ) and relatedness  
241 ( $M_{ajd}= 3.86$ ) than non-mentees ( $M_{ajd}= 3.26$ ;  $M_{ajd}= 3.45$ , respectively). The three psychological  
242 needs predicted all QoL variables.

243 After controlling for sex, paraplegia/tetraplegia, adapted public transportation and  
244 mobility, competence mediated the peer mentorship–participation relationship for autonomous  
245 indoor participation, family role, and autonomous outdoor participation and relatedness was a  
246 mediator for social participation (Table 4; Figures 4 & 5; Supplemental Tables XV-XX). No  
247 other mediation was found. Finally, a brief overview of our sensitivity analysis can be found in  
248 the online supplemental information.

## 249 Discussion

250 This study examined the relationships between SCI peer mentorship and  
251 QoL/participation variables and tested an SDT model with the psychological needs as mediators  
252 of that relationship. Overall, mentees living with SCI for ~30 years appeared to benefit more  
253 from peer mentorship interactions in comparison with non-mentees and mentees living with SCI  
254 for six years or less. However, at lower YSI, non-mentees also reported greater participation than  
255 mentees. The SDT model showed that psychological needs of competence and relatedness were  
256 significant mediators, partly explaining the role of peer mentorship on QoL/participation.

257 For hypothesis 1, our findings were unexpected and contrary to previous SCI peer  
258 mentorship studies<sup>3; 4; 11</sup> as QoL and participation variables did not differ between the mentees  
259 and non-mentees. However, differences existed at specific times in the YSI spectrum, as shown  
260 by the small to medium moderation effects, indicating that mentees with greater YSI reported  
261 higher life satisfaction and greater participation than non-mentees. Therefore, the effects of peer  
262 mentorship on QoL may be more meaningful to individuals who have been living with SCI for

263 longer. While there are not yet published data to support this statement, anecdotal reports from  
264 SCI peer mentorship program leaders suggested that some information shared during peer  
265 mentorship (e.g., parenting with an SCI, reducing social isolation) does not become relevant until  
266 later on. Therefore, adults living with SCI longer may make the most use of peer mentorship, and  
267 thus report slightly greater life satisfaction than mentees with fewer YSI and non-mentees living  
268 with SCI longer. Practically, these results inform SCI community-based organizations utilizing  
269 peer mentorship, who could consider (a) targeting individuals who may not have utilized peer  
270 mentorship early in their injury recovery as they may benefit from mentorship later, and (b)  
271 following-up with previous mentees, especially after many YSI, as they may be more receptive  
272 to mentorship and experience additional benefits.

273         We also found that, contrary to expectations, non-mentees with low YSI reported greater  
274 participation than mentees. This finding may reflect a self-selection bias such that non-mentees  
275 did not seek peer mentorship because they were satisfied with their participation while their  
276 mentee counterparts sought mentorship because their participation was not optimal. Furthermore,  
277 QoL/participation variables may be too broad and distal outcomes for this existing community-  
278 based peer mentorship program because other SCI-related variables may also predict  
279 QoL/participation (e.g., secondary complications<sup>24</sup>). Evidently, more research is needed to  
280 explain these findings. Qualitative research could explore why people do/do not participate in  
281 SCI peer mentorship; measurement studies could identify variables that best capture the benefits  
282 of existing SCI peer mentorship programs. Future studies could also code the participation  
283 variables differently by separating the “No, but I would like to” and “No, but I don’t want to”  
284 response options. As such, different results may emerge, as more weight would be given to  
285 motivated, but non-participating individuals.

286 In hypothesis 2, SDT was partly supported as competence and relatedness mediated some  
287 peer mentorship-QoL/participation relationships. SDT studies in other contexts have  
288 demonstrated the mediating role of competence and relatedness with regard to similar QoL  
289 outcomes, such as positive and negative affect.<sup>25; 26</sup> In addition, the relationship of SCI peer  
290 mentorship with competence is similar to findings in other SCI peer mentorship-related studies  
291 on self-efficacy, a concept analogous to competence.<sup>5; 27</sup> Other peer mentorship studies have also  
292 discussed the importance of relatedness.<sup>11</sup> These findings therefore highlight that if mentors can  
293 enhance the psychological needs of competence and relatedness among their mentees, the  
294 mentees will likely report greater QoL and specific types of participation. On a practical level,  
295 mentors should continue (or start) providing positive feedback, demonstrating new skills, and  
296 structuring their mentorship sessions (e.g., outlining goals and expectations of the sessions) to  
297 enhance competence. Additionally, mentors could continue (or start) involving family in the  
298 mentorship process or introduce mentees to other people with SCI to continue fostering a sense  
299 of belongingness among the people they care about.

### 300 **Limitations and future directions**

301 A limitation of this study is the design. Although a randomized controlled trial would be  
302 ideal, it is difficult to implement in community-based settings with existing programing. Making  
303 an existing service unavailable for some members would be unethical and not supported by the  
304 community organization. Therefore, a static group comparison design remains the most feasible  
305 approach to examine outcomes of an existing community-based SCI peer mentorship program,  
306 acknowledging that we cannot make causal conclusions. To further understand the effectiveness  
307 of peer mentorship, additional studies testing different methods of delivery (e.g., telephone-based  
308 SCI peer mentorship<sup>28</sup>), using other designs (e.g., prospective/longitudinal<sup>27</sup>), examining peer  
309 mentorship training methods,<sup>29</sup> and testing other mediating variables such as types of social

310 support (e.g., instrumental, informational, emotional) are needed. Other limitations included  
311 separately testing the SDT models for each psychological need due to the suppression effects and  
312 imputing the data for four participation variables, warranting caution in the interpretation of  
313 these results. Given our items for physical and psychological health participation were broad (1  
314 item each) and had low reliability, other studies examining more detailed measures of these  
315 constructs may yield different results. Generalizability is also limited as all participants were  
316 recruited from one province in Canada and most responded to an email invitation. Furthermore,  
317 mentees were defined as individuals who received at least four peer mentorship sessions in the  
318 past five years, which may diverge from other programs' definition of peer mentorship. Future  
319 studies could look at the dose-response relationship for mentorship to determine the ideal  
320 number of sessions that lead to improvements in QoL/participation. A self-selection bias in our  
321 sample may be present as individuals who chose to receive peer mentorship may have unique  
322 characteristics (e.g., less SCI-related need met and higher educated).<sup>4</sup> However, such bias does  
323 reflect the realities of existing SCI community-based peer mentorship programs.

## 324 **Conclusion**

325 This study was the first to examine SCI peer mentorship through an SDT lens. It also is the  
326 largest study to date to compare SCI mentees and non-mentees in existing community-based peer  
327 mentorship programs. This study provided some preliminary insight regarding the roles of YSI  
328 and competence and relatedness need satisfaction in relation to key outcomes. However, more  
329 effort is needed to understand how SCI peer mentorship programs foster positive outcomes and  
330 how these processes can be optimized. Such research could provide exciting opportunities for  
331 community-based organizations and researchers to work together to enhance the impact of peer  
332 mentorship on the lives of adults with SCI.

437 Note. Separate analyses were conducted for each psychological need due to suppression effects.  
438 Unstandardized coefficients are presented. Values in parentheses align with the outcome in the  
439 same parenthesis. \*  $p < .05$ . <sup>a</sup> = autonomy, <sup>c</sup> = competence, <sup>r</sup> = relatedness values for separate  
440 analyses.

441 **Figure 4.** Figure 4. Self-determination theory model predicting autonomous participation  
442 variables.

443 Note. Separate analyses were conducted for each psychological need due to suppression effects.  
444 Unstandardized coefficients are presented. Values in parentheses align with the outcome in the  
445 same parenthesis. \*  $p < .05$ ; †  $p = .05$ . <sup>a</sup> = autonomy, <sup>c</sup> = competence, <sup>r</sup> = relatedness values for  
446 separate analyses.

447 **Figure 5.** Self-determination theory model predicting social relationship and family role  
448 participation variables.

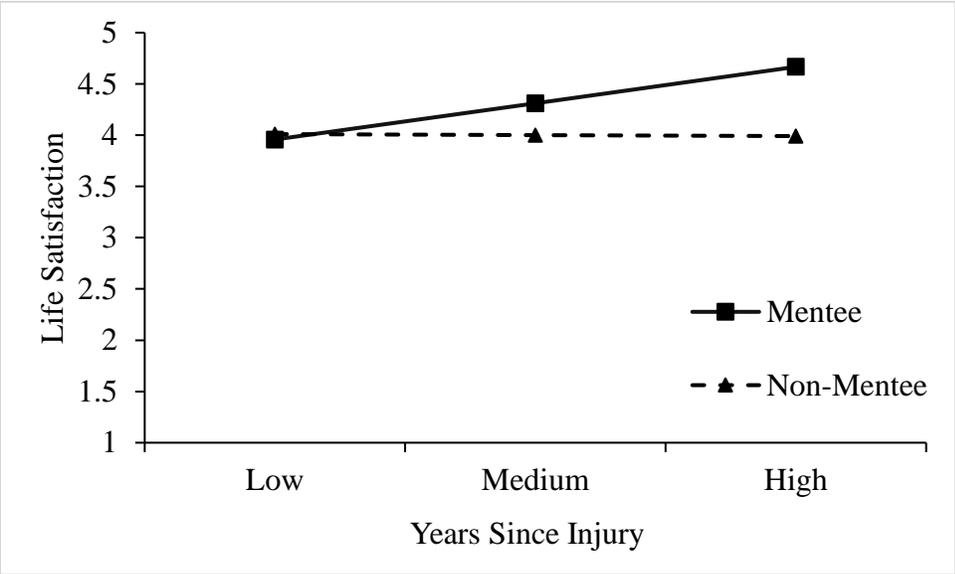

449 Note. Separate analyses were conducted for each psychological need due to suppression effects.  
450 Unstandardized coefficients are presented. Values in parentheses align with the outcome in the  
451 same parenthesis. \*  $p < .05$ . <sup>a</sup> = autonomy, <sup>c</sup> = competence, <sup>r</sup> = relatedness values for separate  
452 analyses.

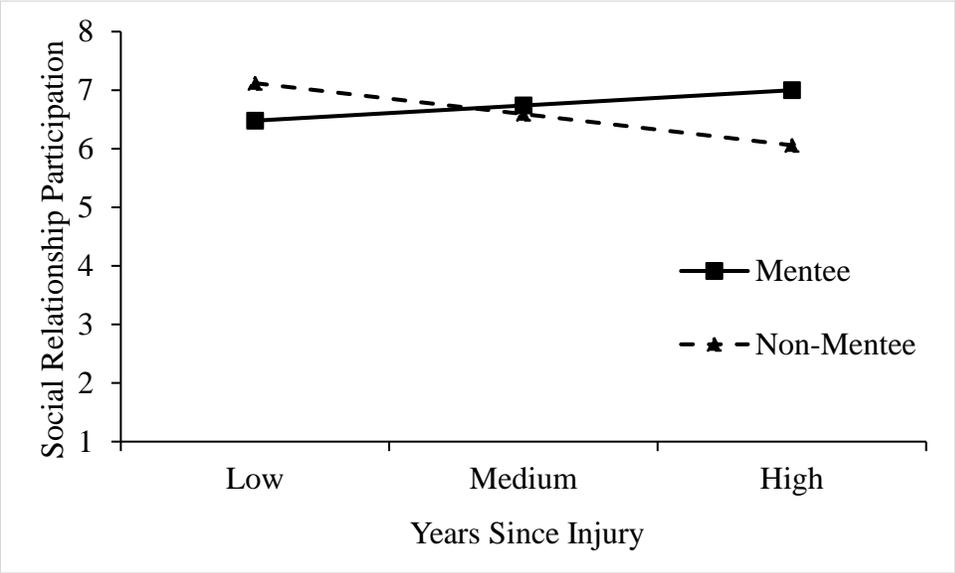

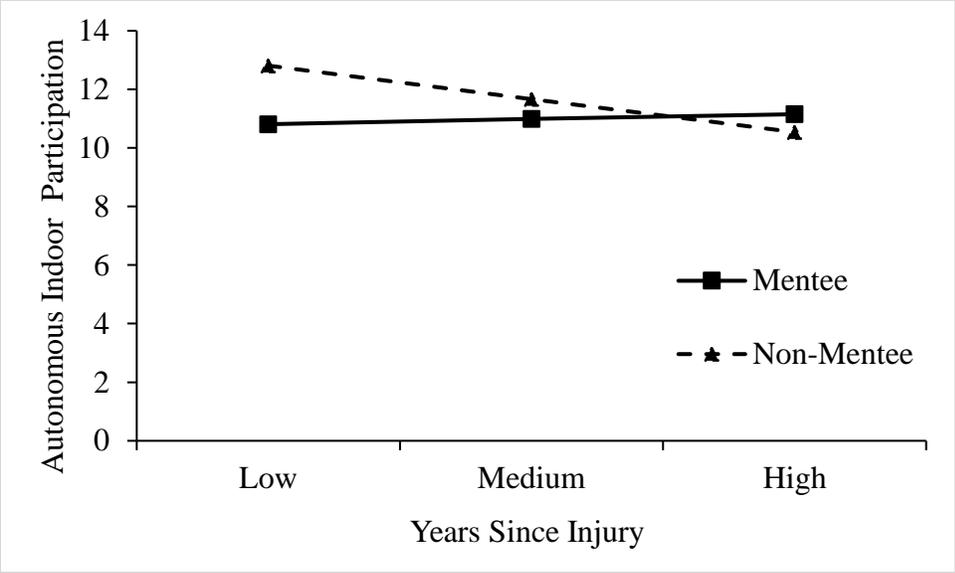

453

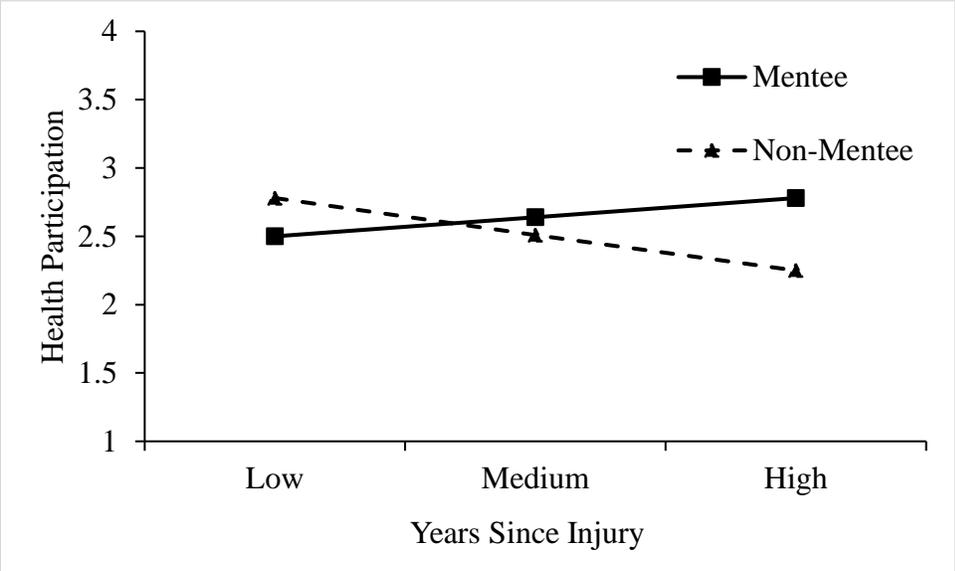

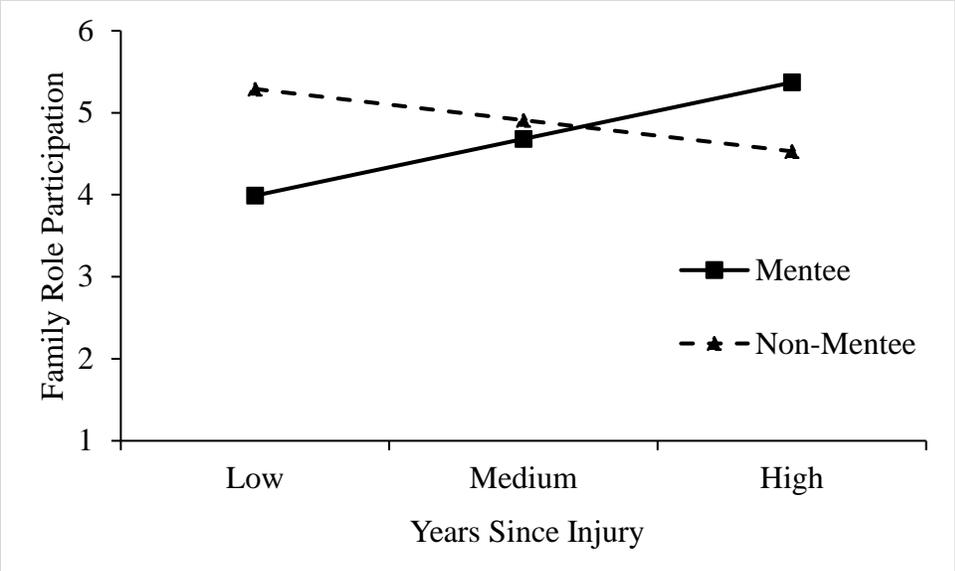

---

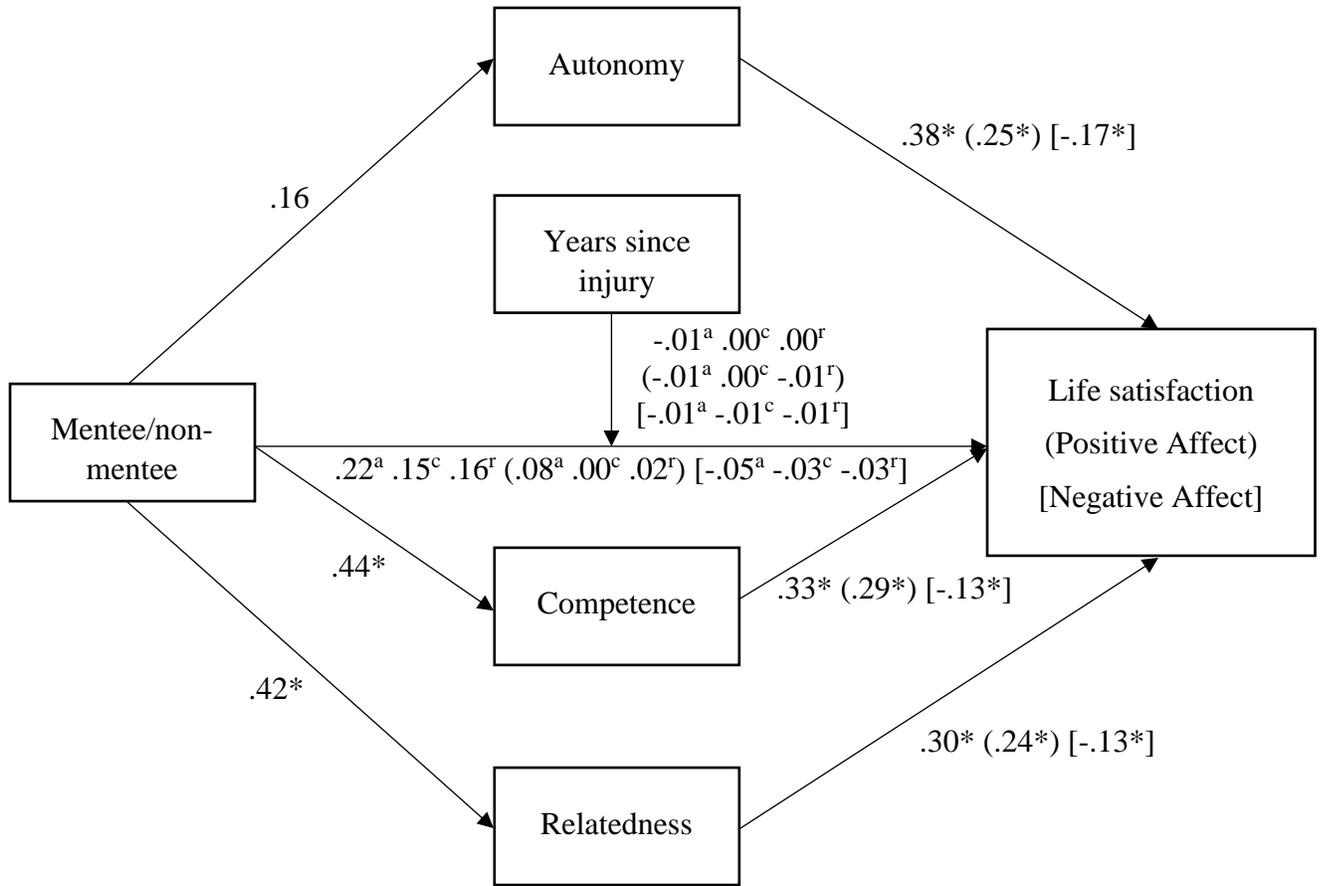

<sup>i</sup> Peer mentors and the directors of the organization indicated that meaningful discussions and mentorship about the life of the mentees typically started on the fourth interaction and onwards. The first and second interactions are typically short, introductory discussions.

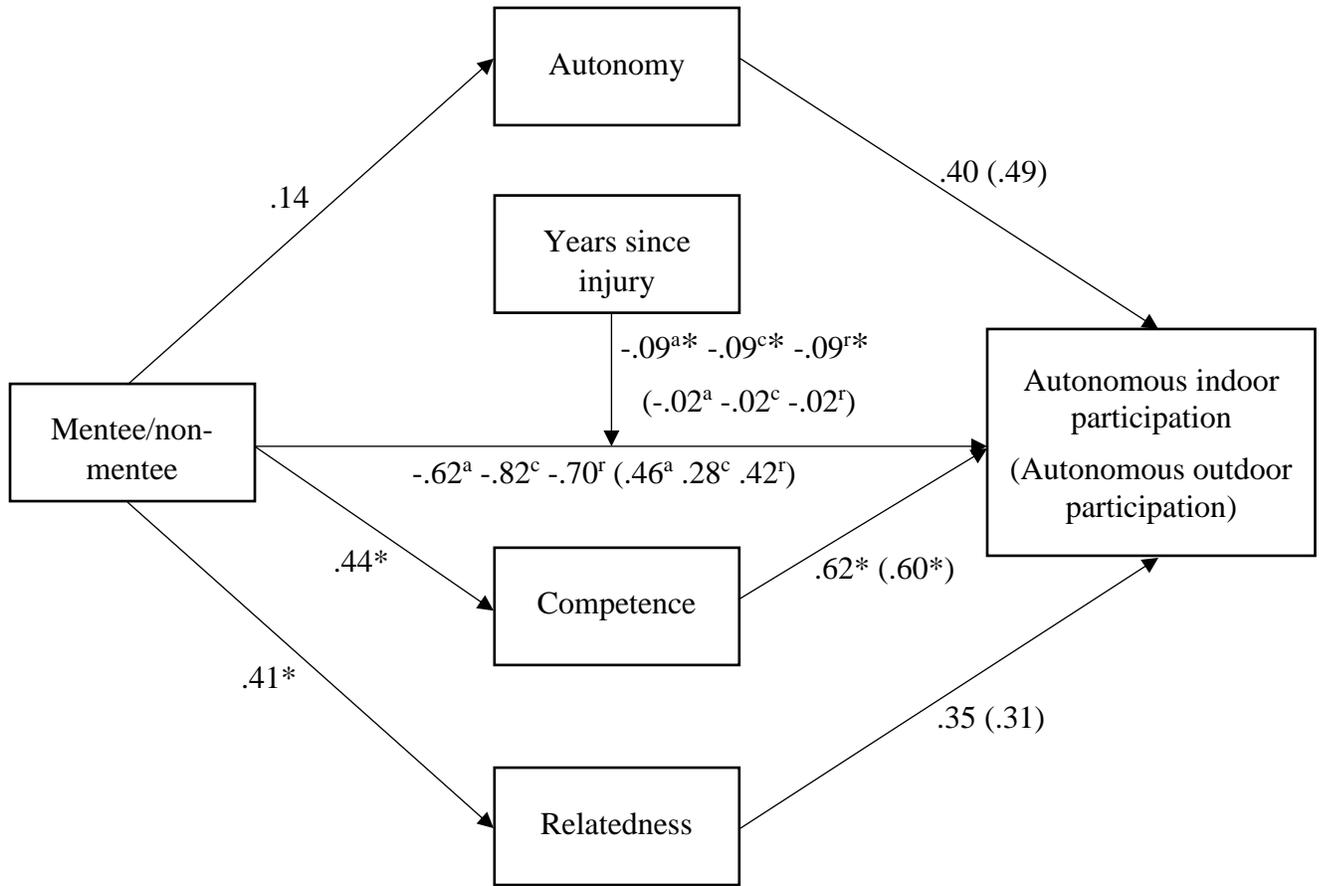

<sup>ii</sup> The square root transformation for participation social relationship rendered the same result,  $F(1, 125) = .49, p = .49, \eta^2 = .004$ .

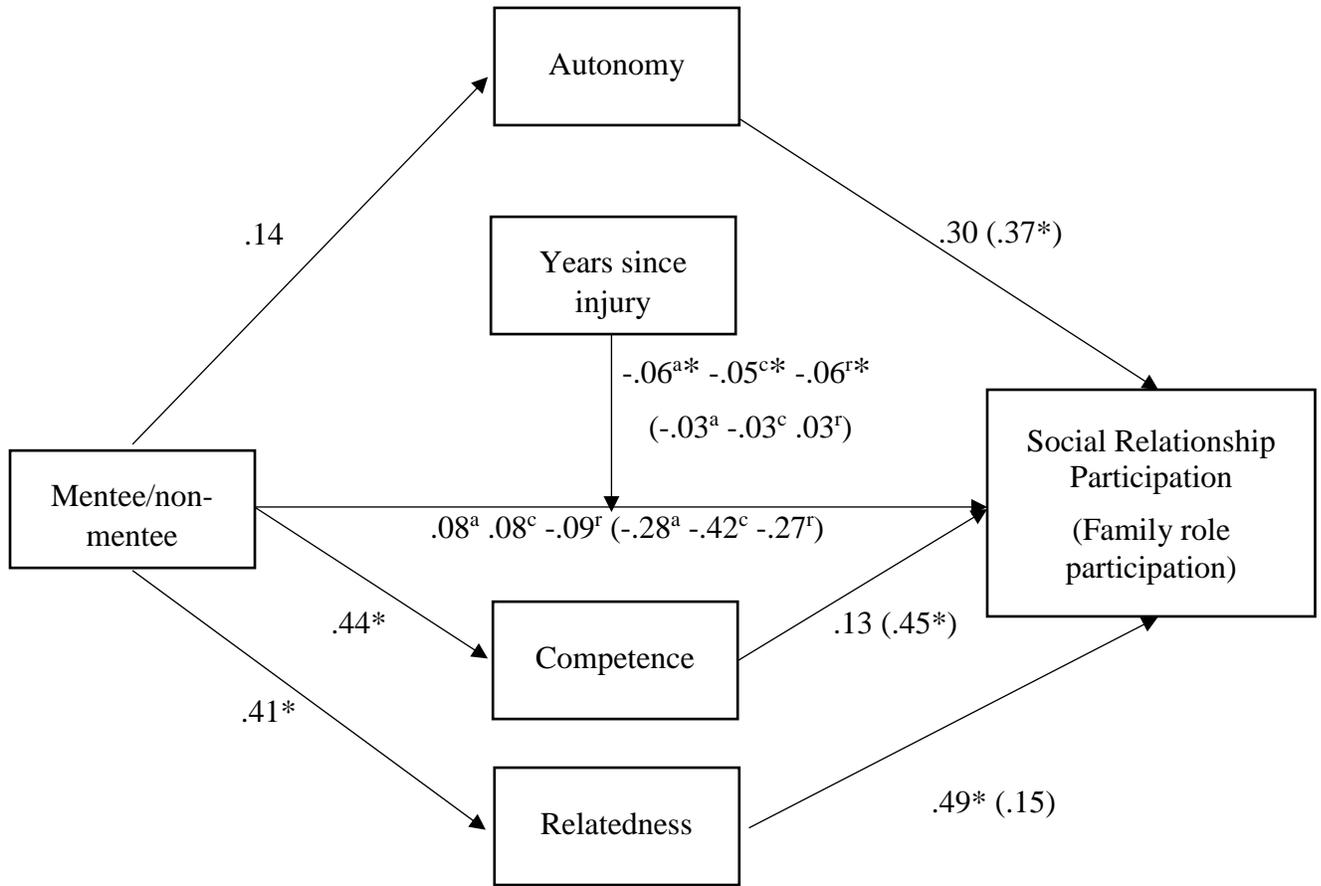

Table 1. Demographic and spinal cord injury variables by mentees and non-mentees

	Mentees	Non- mentees		
Continuous variables	Means (SD)	Means (SD)	t-test (df)	Cohen's d
Age	50.0 (12.9)	53.0(12.3)	1.36(129)	0.24
Years since injury	14.1(13.5)	20.1(12.8)	2.59(129)*	0.46
Categorical variables	n (%)	n (%)	X <sup>2</sup> (df)	Cramer's V
Gender				
Male	48 (72)	46 (73)	.03(1)	.02
Female	19 (28)	17 (27)		
Ethnicity				
White	64 (94)	62 (98)	1.64(1)	.11
Other	4 (6)	1 (2)		
Marital Status				
Single/Divorced/Widowed	33 (49)	37 (59)	1.37(1)	.10
Married or Common law	35 (51)	26 (41)		
Education				
High School or lower	23 (34)	29 (46)	4.76(3)	.19
Post-secondary	45 (66)	33 (52)		
ASIA				
A	32 (47)	25 (40)	3.20(4)	.17

Table 2. Group differences on quality of life and participation variables

Variables	Mentees	Non-Mentees	F (dfs)	p	Partial eta-square
	Means (SD)	Means (SD)			
Life satisfaction	4.22 (.90)	4.01 (.90)	2.24 (1,120)	.14	.02
Positive affect	3.50 (.82)	3.40 (.69)	0.62 (1,120)	.43	<.01
Negative affect	1.89 (.68)	1.98 (.67)	0.10 (1,120)	.76	<.01
Participation					
Autonomous indoors	10.79 (3.32)	11.59 (3.31)	0.70 (1, 123)	.40	.01
Autonomous outdoors	7.60 (3.06)	7.37 (2.53)	0.01 (1, 127)	.92	<.01
Social relationship	6.76 (1.20)	6.39 (1.63)	0.69 (1, 125)	.41	.01
Family role	4.47 (2.06)	4.88 (2.03)	0.62 (1, 123)	.43	.01
Health	2.59 (.94)	2.48 (1.02)	0.81 (1, 128)	.37	.01
Work/Education	2.04 (1.76)	2.05 (1.82)	0.15 (1, 127)	.70	<.01

Note. The values presented are unadjusted for the covariates.

Table 3. Interaction coefficients (B), variance ( $R^2$ ), change in variance ( $\Delta R^2$ ) and significance (95% bias corrected confidence intervals (bCI)) of the moderation between SCI peer mentorship and years since injury on quality of life and participation variables

Outcome variables	B	95% bCI		$R^2$	$\Delta R^2$
		Lower bCI	Upper bCI		
Life satisfaction	.03	0.003	0.05	.14	.04
Positive affect	.02	-.003	.04	.11	.02
Negative affect	-.01	-.02	.01	.17	.003
Participation					
Autonomous indoors	.10	.02	.18	.33	.03
Autonomous outdoors	.07	-.004	.15	.10	.03
Social relationship	.06	.03	.10	.23	.07
Family role	.08	.03	.14	.17	.06
Health	.03	.01	.06	.08	.04
Work/Education	.03	-.02	.08	.06	.01

Note. Significance is determined when the 95% bCI does not cross 0.  $\Delta R^2$  = variance explained by the interaction term only (beyond the covariates and the main effects of SCI peer mentorship and YSI)

Table 4. Indirect effect coefficients (B) and significance (95% bias corrected confidence intervals (bCI)) of the competence and relatedness need satisfaction of self-determination theory between SCI peer mentorship and the quality of life and participation variables.

Outcome variables	Competence			Relatedness		
	B	95% bCI		B	95% bCI	
		Lower bCI	Upper bCI		Lower bCI	Upper bCI
Life satisfaction	.15	.04	.32	.13	.01	.29
Positive affect	.13	.02	.26	.10	.01	.22
Negative affect	-.06	-.14	.00	-.05	-.15	.00
Participation						
Autonomous indoors	.28	.04	.73	.14	-.04	.51
Autonomous outdoors	.27	.04	.63	.13	-.06	.52
Social relationship	.06	-.04	.26	.20	.02	.47
Family role	.20	.03	.53	.06	-.07	.33
Health	.03	-.04	.12	.03	-.03	.17
Work/Education	.11	.03	.78	.01	-.21	.22

Note. Significance is determined when the 95% bCI does not cross 0.
